ON STRONGLY ASYMPTOTIC ℓ_p SPACES AND MINIMALITY

S. J. DILWORTH, V. FERENCZI, DENKA KUTZAROVA AND E. ODELL

Abstract

Let $1 \leqslant p \leqslant \infty$ and let X be a Banach space with a semi-normalized strongly asymptotic ℓ_p basis (e_i). If X is minimal and $1 \leqslant p < 2$, then X is isomorphic to a subspace of ℓ_p. If X is minimal and $2 \leqslant p < \infty$, or if X is complementably minimal and $1 \leqslant p \leqslant \infty$, then (e_i) is equivalent to the unit vector basis of ℓ_p (or c_0 if $p = \infty$).

1. *Introduction*

The notion of minimality was introduced by Rosenthal. An infinite-dimensional Banach space X is minimal if every infinite-dimensional subspace has a further subspace isomorphic to X.

Let $1 \leqslant p \leqslant \infty$. A Banach space X with a basis (e_i) is *asymptotic* ℓ_p [**34**] if there exist $C < \infty$ and an increasing function $f : \mathbb{N} \to \mathbb{N}$ such that, for all $n \in \mathbb{N}$, every normalized block basis $(x_i)_{i=1}^n$ of $(e_i)_{i=f(n)}^\infty$ is C-equivalent to the unit vector basis of ℓ_p^n. In this case (e_i) is called an asymptotic ℓ_p basis for X.

The only known examples of minimal spaces were ℓ_p ($1 \leqslant p < \infty$) and c_0 and their subspaces until the original Tsirelson space T^* [**11**], which is *asymptotic* ℓ_∞, was shown to be minimal [**11**]. Tsirelson's space T is asymptotic ℓ_1 and does not contain a minimal subspace [**9**].

The next minimal space was constructed by Schlumprecht [**39**], and in [**12**] a superreflexive version of S was given. Both versions are actually complementably minimal, that is, every infinite-dimensional subspace has a complemented subspace isomorphic to the whole space. Gowers [**21**] included minimality in his partial classification of Banach spaces, which motivated a series of results relating minimality to subsymmetry [**35**], or to the number of non-isomorphic (respectively, incomparable) subspaces of a Banach space [**15**, **19**] (respectively [**37**]).

We shall call a Banach space X with a basis (e_i) *strongly asymptotic* ℓ_p if there exist $C < \infty$ and an increasing function $f : \mathbb{N} \to \mathbb{N}$ such that, for all $n \in \mathbb{N}$, every normalized sequence $(x_i)_{i=1}^n$ of disjointly supported vectors from $[(e_i)_{i=f(n)}^\infty]$ is C-equivalent to the unit vector basis of ℓ_p^n.

In [**9**], it was proved that the standard bases of T and its strongly asymptotic version (sometimes called modified Tsirelson's space) are equivalent. A new class of strongly asymptotic ℓ_p spaces was introduced in [**4**]. Sufficient conditions for selecting strongly asymptotic ℓ_p subspaces of a given Banach space were given in [**20**, **40**].

Our main results are proved in Section 3 (Theorem 9) and Section 4 (Theorem 14). We summarize these results in slightly weaker form in Theorem 1.

Theorem 1. *Let $1 \leqslant p \leqslant \infty$ and let X be a Banach space with a semi-normalized strongly asymptotic ℓ_p basis (e_i);*

- *if X is minimal and $1 \leqslant p < 2$, then X is isomorphic to a subspace of ℓ_p,*
- *if X is minimal and $2 \leqslant p < \infty$, or if X is complementably minimal and $1 \leqslant p \leqslant \infty$, then (e_i) is equivalent to the unit vector basis of ℓ_p (or c_0 if $p = \infty$).*

For $1 \leqslant p < 2$, we also give examples of strongly asymptotic ℓ_p basic sequences in ℓ_p spanning minimal spaces that are not isomorphic to ℓ_p (Theorem 12).

Recall again that T^* is a minimal space which is strongly asymptotic ℓ_∞.

QUESTION 2. Does there exist a minimal asymptotic ℓ_p space that does not embed into ℓ_p for $1 \leqslant p < \infty$?

A broader definition of 'asymptotic ℓ_p space' which is independent of a basis is given in [**33**]. The definition is that for some $C < \infty$ and for all $n \in \mathbb{N}$, if $(e_i)_1^n \in \{X\}_n$, where $\{X\}_n$ is the nth asymptotic class selected via the filter of finite-codimensional subspaces, then $(e_i)_1^n$ is C-equivalent to the unit vector basis of ℓ_p^n. This notion does not seem to lend itself to a strongly asymptotic version. But these spaces contain asymptotic ℓ_p basic sequences.

We use standard Banach space theory notation and terminology as in [**31**]. All subspaces (of a Banach space X) are assumed to be closed and infinite-dimensional unless stated otherwise. Let (e_i) be a basis for X. We say that a sequence (x_k) of non-zero vectors is a block basis if there exist integers $0 = n_0 < n_1 < \cdots$ and scalars (a_i) such that

$$x_k = \sum_{i=n_{k-1}+1}^{n_k} a_i e_i \quad (k \geqslant 1).$$

The closed linear span of a block basis is called a block subspace.

A minimal space is C-minimal if every subspace of X contains a C-isomorphic copy of X, that is, there exist $W \subseteq X$ and an isomorphism $T\colon X \to W$ with $\|T\|\|T^{-1}\| \leqslant C$. Casazza [**7**] proved that a minimal space must be C-minimal for some $C < \infty$.

Ferenczi and Rosendal [**19**] defined a space X with a basis (e_i) to be block minimal (respectively, C-block minimal) if every block subspace of X has a further block subspace isomorphic (respectively, C-isomorphic) to X; also X is defined to be equivalence block minimal (respectively, C-equivalence block minimal) if every block basis has a further block basis equivalent (respectively, C-equivalent) to (e_i). They proved that every block minimal (respectively, equivalence block minimal) space is C-block minimal (respectively, C-equivalence block minimal) for some $C < \infty$; they deduced that a basis which is asymptotic ℓ_p for $1 \leqslant p \leqslant \infty$ (in the broader sense associated to the filter of tail subspaces) and equivalence block minimal must be equivalent to the unit vector basis of ℓ_p or c_0.

We remark that T^* is minimal but does not contain any block minimal block subspace. Indeed, recall [**10**] that any block basis of T^* is equivalent to a subsequence of the standard basis (t_n^*) and that the subspaces $[(t_{n_k}^*)]$ and $[(t_{m_k}^*)]$ are isomorphic if and only if $(t_{n_k}^*)$ and $(t_{m_k}^*)$ are equivalent. Thus, if T^* had a block minimal block subspace $[(x_i^*)]$, then $[(x_i^*)]$ would be equivalence block minimal and therefore C-equivalence block minimal for some $C < \infty$. That, combined with (x_i^*) being an asymptotic ℓ_∞ basis, would imply that (x_i^*) is equivalent to the unit vector basis of c_0, which is a contradiction since T^* does not contain c_0.

2. *Asymptotic ℓ_p subspaces of L_p*

Our reference for results concerning L_p will mostly be the survey article by Alspach and Odell [**1**]. For the definition and properties of the Haar basis (h_i), we take [**32**, Section 2.c] as our reference.

We note that every strongly asymptotic ℓ_p sequence (e_i) is unconditional. Indeed, if x and y are disjointly supported vectors belonging to $[(e_i)_{i \geqslant f(2)}]$, then

$$\|x \pm y\| \approx (\|x\|^p + \|y\|^p)^{1/p},$$

which implies unconditionality.

Let X be a Banach space with a basis (e_i). A blocking of (e_i) is a *finite-dimensional decomposition* (*FDD*) for X corresponding to a partition $\{F_n : n \in \mathbb{N}\}$ of $\mathbb{N}$ into successive finite subsets, that is, $X = \sum_{n=1}^{\infty}[e_i : i \in F_n]$. Let $T_\omega = \{(n_1, \dots, n_k) \in \mathbb{N}^k : k \in \mathbb{N}\}$ be the countably branching tree ordered by $(n_1, \dots, n_k) \leqslant (m_1, \dots, m_l)$ if $k \leqslant l$ and $n_i = m_i$ for $i \leqslant k$. We say that $T \in T_\omega(X)$ if $T = \{x_{(n_1,\dots,n_k)} : (n_1, \dots, n_k) \in T_\omega\} \subset S_X$. Further, T is a block tree with respect to the basis (e_i) if in addition $(x_{(n)})_{n\in\mathbb{N}}$ and $(x_{(n_1,\dots,n_k,n)})_{n\in\mathbb{N}}$ are all block bases of (e_i) for all $(n_1, \dots, n_k) \in T_\omega$.

Proposition 3. *Let $1 < p < \infty$ and let X be a subspace of $L_p[0, 1]$ with an semi-normalized asymptotic ℓ_p basis (e_i). Then X embeds into ℓ_p. If $p \geqslant 2$ and (e_i) is strongly asymptotic ℓ_p, then (e_i) is actually equivalent to the unit vector basis of ℓ_p.*

Proof. We may of course assume that $p \neq 2$. Then the space X does not contain a subspace isomorphic to ℓ_2, otherwise some block basis of (e_i) would be equivalent to the unit vector basis of ℓ_2, contradicting the fact that (e_i) is asymptotic ℓ_p. If $p > 2$ this implies by Alspach and Odell [**1**, Theorem 30] that X embeds into ℓ_p (in fact, $X(1+\varepsilon)$-embeds into ℓ_p for all $\varepsilon > 0$ [**29**]). Assume now that $1 < p < 2$. By a theorem of Johnson (see e.g. [**1**, Theorem 30]), it suffices to prove that for some $C < \infty$ every normalized block basis (x_i) of (e_i) admits a subsequence C-equivalent to the unit vector basis of ℓ_p. Passing to a subsequence we may assume that (x_i) is a perturbation of a block basis of the Haar basis and hence is $C(p)$-unconditional for some constant $C(p)$ depending only on p [**32**, Theorem 2.c.5]. By Alspach and Odell [**1**, Lemma 28], it suffices to show that there exist $\delta(K) > 0$, where K is the asymptotic ℓ_p-constant of (e_i), $(y_i) \subseteq (x_i)$ and disjoint measurable sets E_i in $[0, 1]$ with $\|y_{i|E_i}\| \geqslant \delta(K)$ for all i.

By a theorem of Dor [**13**] there exists $\delta(K) > 0$ such that if $(x_i)_{i\in A}$ is K-equivalent to the unit vector basis of $\ell_p^{|A|}$ then there exist disjoint measurable sets $(F_i)_{i\in A}$ in $[0, 1]$ with $\|x_{i|F_i}\| > \delta(K)$ for $i \in A$. Since (e_i) is K-asymptotic ℓ_p we can thus, for all n and $\varepsilon > 0$, choose $i > n$ and a measurable set F_i with $\lambda(F_i) < \varepsilon$ (where λ denotes Lebesgue measure) and $\|x_{i|F_i}\| > \delta(K)$. We then proceed inductively. Let $y_1 = x_1$ and $F_1^1 = [0, 1]$. Assume that $(y_1, \dots, y_n)$ have been chosen along with disjoint sets $F_1^n, \dots, F_n^n$ so that $\|y_{i|F_i^n}\| > \delta(K)$. Applying the above for a suitable ε, using the uniform integrability of $(|y_i|^p)_{i=1}^n$, we can choose y_{n+1} and F_{n+1}^{n+1} so that $\|y_{n+1|F_{n+1}^{n+1}}\| > \delta(K)$, $(y_i)_1^{n+1}$ is a subsequence of (x_i), and $\|y_{i|F_i^{n+1}}\| > \delta(K)$ for $i \leqslant n$, where $F_i^{n+1} = F_i^n \setminus F_{n+1}^{n+1}$. The claim now follows by setting $E_i = \bigcap_{n\geqslant i} F_i^n$.

Finally, assume that $p > 2$ and that (e_i) is strongly asymptotic ℓ_p with constant $C < \infty$ and an associated function f. As we noted, (e_i) is unconditional. By Dor and Starbird [**14**] (see also [**25**] or [**32**, Corollary 2.e.19] for a more general lattice version), a normalized unconditional sequence (x_i) in L_p is either equivalent to the unit vector basis of ℓ_p, or it has, for all $n \in \mathbb{N}$, n disjoint normalized blocks, which form a sequence 2-equivalent to the unit vector basis of ℓ_2^n.

Let $k \in \mathbb{N}$ be such that the unit vector bases of ℓ_2^k and ℓ_p^k are not $2C$-equivalent. Since (e_i) is strongly asymptotic ℓ_p, there cannot exist a normalized length k sequence of disjoint blocks on $(e_i)_{i\geqslant f(k)}$ which is 2-equivalent to the basis of ℓ_2^k. So $(e_i)_{i\geqslant f(k)}$, and therefore (e_i), is equivalent to the unit vector basis of ℓ_p. □

Note that it remains open whether we may remove 'strongly' from the last part of Proposition 3.

Question 4. Does there exist an unconditional asymptotic ℓ_p basic sequence in L_p, $p > 2$, which is not equivalent to the unit vector basis of ℓ_p?

PROPOSITION 5. *Let X be a subspace of $L_1[0, 1]$. If X has an unconditional asymptotic ℓ_1 basis then X embeds into ℓ_1.*

Proof. Let (e_i) be an unconditional asymptotic ℓ_1 basis for X. Then (e_i) is necessarily boundedly complete, so by Alspach and Odell [**1**, Proposition 31], it suffices to prove that for some $C < \infty$ if $T \in T_\omega(X)$ is a block tree with respect to (e_i) then some branch of T is C-equivalent to the unit vector basis of ℓ_1. The proof of this is much like the previous proof in the case $1 < p < 2$. We need only show that there exists $\delta = \delta(K) > 0$ so that for all such T we can find a branch (y_i) and disjoint measurable sets (E_i) with $\|y_{i|E_i}\| > \delta$ for all i. Again we use Dor's theorem. If $(y_i)_1^n$ have been chosen as an initial segment in T along with disjoint sets $(F_i^n)_{i=1}^n$ satisfying $\|y_{i|F_i^n}\| > \delta$ for $i \leqslant n$, then we can select y_{n+1} from among the successors of y_n and F_{n+1}^{n+1} with $\|y_{n+1|F_{n+1}^{n+1}}\| > \delta$ and $\lambda(F_{n+1}^{n+1})$ as small as we please. In particular, we may ensure that $\|y_{i|F_i^n \setminus F_{n+1}^{n+1}}\| > \delta$ for $i \leqslant n$. Then as earlier we let $E_i = \bigcap_{n \geqslant i} F_i^n$. $\square$

REMARKS 6. (1) We do not know if Proposition 5 holds if we merely assume that (e_i) is asymptotic ℓ_1. Then (e_i) would still be boundedly complete but we need unconditionality to conclude that the branch (y_i) with $\|y_{i|E_i}\| > \delta$ is $C(K)$-equivalent to the unit vector basis of ℓ_1 using the work of Alspach and Odell [**1**, Lemma 28].

However, we can drop 'unconditionality' in any of the following three cases:

(a) (e_i) is a block basis of (h_i) or more generally for all $n \in \mathbb{N}$

$$\lim_{m \to \infty} \sup\{\|P_n x\| \colon x \in B_{[e_i]_{i=m}^\infty}\} = 0,$$

where P_n is the basis projection of $L_1[0, 1]$ onto the span of the first n Haar functions;

(b) for some $K < 2$ every normalized block basis of (e_i) admits a subsequence K-equivalent to the unit vector basis of ℓ_1;

(c) (e_i) is K-asymptotic ℓ_1 with $K < 2$.

Indeed, the branch (y_i) obtained in the proof can be chosen so that

$$\|\sum_i a_i y_i\| \geqslant \|\sum_i a_i y_{i|\cup_j E_j}\| \gtrsim \sum_i \|a_i y_{i|E_i} + \sum_{j>i} a_j y_{j|E_i}\|.$$

Now under (a) we can also choose (y_i) so that, for all i, $(y_{j|E_i})_{j \geqslant i}$ is 2-basic and so

$$\|a_i y_{i|E_i} + \sum_{j>i} a_j y_{j|E_i}\| \geqslant \frac{1}{2}|a_i|\|y_{i|E_i}\| \geqslant \frac{1}{2}|a_i|\delta.$$

Next we shall show that case (b) yields that we can choose the branch (y_i) and sets (E_i) so that $\|y_{i|E_i}\| > \delta > 1/2$ if $1/2 < \delta < 1/K$. Since

$$\begin{aligned}\sum_i \|a_i y_{i|E_i} + \sum_{j>i} a_j y_{j|E_i}\| &\geqslant \sum_i \Big(|a_i|\delta - \sum_{j>i} |a_j|\|y_{j|E_i}\|\Big)\\ &\geqslant \delta \sum_i |a_i| - \sum_i |a_i|\|y_{i|[0,1]\setminus E_i}\|\\ &\geqslant (\delta - (1-\delta)) \sum_i |a_i| = (2\delta - 1)\sum_i |a_i|,\end{aligned}$$

we obtain that (y_i) is equivalent to the unit vector basis of ℓ_1.

Suppose that (x_i) is a normalized block basis of (e_i) and (b) holds. Passing to a subsequence, we may assume that (x_i) is K-equivalent to the unit vector basis of ℓ_1. Moreover by Rosenthal's 'subsequence splitting lemma' (see, for example, [**22**] or [**25**, p. 135] for a general lattice version), we may assume that $(x_i) = (u_i + z_i)$, where $(z_i) = (x_{i|E_i})$ is disjointly supported, $\lim_i \|z_i\| = b$, and $(|u_i|)$ is uniformly integrable. It suffices to prove that $b \geqslant 1/K$. For then the proof of Proposition 5 will yield the $\|y_{i|E_i}\| > \delta$ claim. Given $\varepsilon > 0$, we can form an absolute convex combination $\sum_i a_i x_i$ with $\|\sum_i a_i u_i\| < \varepsilon$, and thus $\|\sum_i a_i z_i\| = \sum_i |a_i|\|z_i\| \geqslant 1/K - \varepsilon$. Since these can be found arbitrarily far out we deduce that $b \geqslant 1/K$.

Finally assume (c) holds. Let (x_i) again be a normalized block basis of (e_i). We may assume, passing to a subsequence, as in case (b) that $(x_i) = (u_i + z_i)$, $(z_i) = (x_{i|E_i})$ is disjointly supported, $\lim_i \|z_i\| = b$, $(|u_i|)$ is uniformly integrable, and moreover $u_i = u + v_i$, where (v_i) is a weakly null perturbation of a block basis of the Haar basis for $L_1[0, 1]$. We assume $\|v_i\| \to a \in [0, 2]$ and first assume $a \neq 0$. Passing again to a subsequence we may assume (v_i) has a spreading model $(\tilde{v}_i)$ which is unconditional, subsymmetric, and (for example, by Dor's theorem [**13**]) is not equivalent to the unit vector basis of ℓ_1. Thus $\lim_n (1/n)\|\sum_{i=1}^n \tilde{v}_i\| = 0$ (see, for example, [**5**]). In particular, we can thus find (even if $a = 0$) for all $\varepsilon > 0$ an absolute convex combination $\sum_{i \in E_\varepsilon} a_i^\varepsilon x_i$ with $\|\sum_{E_\varepsilon} a_i^\varepsilon u_i\| < \varepsilon$ and $f(|E_\varepsilon|) \leqslant \min E_\varepsilon$, where f is the function associated to the asymptotic ℓ_1 sequence (e_i). As in case (b), we deduce that $b \geqslant 1/K$ and finish the proof as in case (b).

(2) Note that if (e_i) is a K-asymptotic ℓ_1 basis for $X \subset L_1[0, 1]$, then X has the strong Schur property. To see this, let $\delta > 0$ and let (x_i) be a sequence in B_X satisfying $\|x_i - x_j\| \geqslant \delta$. Since (e_i) is boundedly complete, we may assume (by passing to a subsequence) that $x_i = y + z_i$, where $y, z_i \in X$ and (z_i) is a perturbation of a block basis of (e_i). We may assume that $\|z_i\| \to a \geqslant \delta/2$ and that $(z_i/\|z_i\|)$ is K'-asymptotic ℓ_1, where $K' > K$ is arbitrary. As in (1) we may also assume, by passing to a subsequence, that there exist disjoint sets (E_i) with $\lim_i \|(z_i/\|z_i\|)_{|E_i}\| = b \geqslant 1/K'$ and so $\lim_i \|z_{i|E_i}\| = ab \geqslant \delta/(2K')$. By Rosenthal's lemma [**38**], some subsequence of (z_i) is $(4K'/\delta)$-equivalent to the unit vector basis of ℓ_1. Hence a subsequence of (x_i) is $(4K'(B+2)/\delta)$-equivalent to the unit vector basis of ℓ_1, where B is the basis constant of (e_i).

In [**6**] some 1-strong Schur subspaces of $L_1[0, 1]$, which do not embed into ℓ_1 are constructed.

(3) Let (E_i) be an FDD for a Banach space X. We say that (E_i) is an asymptotic ℓ_p (respectively, strongly asymptotic ℓ_p) FDD if there exist $C < \infty$ and an increasing function $f : \mathbb{N} \to \mathbb{N}$ such that, for all $n \in \mathbb{N}$, every normalized block basis (respectively, sequence of disjointly supported vectors) $(x_i)_{i=1}^n$ of $[(E_i)_{i=f(n)}^\infty]$ is C-equivalent to the unit vector basis of ℓ_p^n. The proof of Proposition 3 carries over to show that if X is a subspace of L_p $(1 < p < \infty)$ with an asymptotic ℓ_p FDD then X embeds into ℓ_p. Similarly, Proposition 5 remains valid if 'basis' is replaced by 'FDD'.

3. *Strongly asymptotic ℓ_p spaces and primary minimality*

A key ingredient of the proof of Theorem 9 is a uniformity lemma about embedding into subspaces generated by tail subsequences of a basis $(e_i)_{i \in \mathbb{N}}$ (that is, subsequences of the form $(e_i)_{i \geqslant k}$ for $k \in \mathbb{N}$).

We recall that a Banach space X is said to be primary if, whenever $X = Y \oplus Z$, then either X is isomorphic to Y or X is isomorphic to Z.

Definition 7. A Schauder basis $(e_n)_{n \in \mathbb{N}}$ is said to be primarily minimal if, whenever (I, J) is a partition of $\mathbb{N}$, then either $[e_n]_{n \in \mathbb{N}}$ embeds into $[e_n]_{n \in I}$ or $[e_n]_{n \in \mathbb{N}}$ embeds into $[e_n]_{n \in J}$. A Banach space X is primarily minimal if, whenever $X = Y \oplus Z$, then either X embeds into Y or X embeds into Z.

Obviously any unconditional basis of a primarily minimal space must be primarily minimal. Also, the class of primarily minimal spaces contains the class of primary spaces as well as the class of minimal spaces.

PROPOSITION 8. *Let X be a Banach space with a primarily minimal basis $(e_n)_{n\in\mathbb{N}}$. Then there exists $C<\infty$ such that X C-embeds into all of its tail subspaces.*

Proof. Let 2^ω be equipped with its usual topology, that is, basic open sets are of the form $N(u)=\{\alpha=(\alpha_k)_{k\in\mathbb{N}}\in 2^\omega : \forall k\leqslant m, \alpha_k=u_k\}$, where $u=(u_k)_{k\leqslant m}$ is a sequence of 0s and 1s of length m.

Let A be the set of αs in 2^ω such that X embeds into $[e_i]_{\alpha_i=1}$, and let A' be the set of αs in 2^ω such that X embeds into $[e_i]_{\alpha_i=0}$. We also let, for $n\in\mathbb{N}$, A_n (respectively, A'_n) be the set of αs such that X n-embeds into $[e_i]_{\alpha_i=1}$ (respectively, $[e_i]_{\alpha_i=0}$).

Now (e_n) being primarily minimal means that $2^\omega=A\cup A'=(\bigcup_{n\in\mathbb{N}}A_n)\cup(\bigcup_{n\in\mathbb{N}}A'_n)$. By the Baire category theorem, we deduce that the closure of A_N or A'_N has non-empty interior for some $N\in\mathbb{N}$, and hence A_N or A'_N is dense in some basic neighborhood. We note that the map $f:2^\omega\to 2^\omega$ defined by $f((\alpha_i)_{i\in\mathbb{N}})=(1-\alpha_i)_{i\in\mathbb{N}}$ is a homeomorphism such that $f(A_N)=A'_N$. It follows that A_N is dense in some basic neighborhood. Let $u=(u_i)_{i\leqslant m}$ be such that A_N is dense in $N(u)$.

Let $E=\{i:u_i=1, i\leqslant m\}$. It follows that X N-embeds into $[(e_i)_{i\in E}\cup(e_i)_{i>k}]$ for all $k\in\mathbb{N}$. Using the uniform equivalence between $(e_i)_{i\in E}$ and $(e_i)_{i\in F}$ for all $|F|=|E|$, we see that there exists C such that X C-embeds into $[(e_i)_{i>k}]$ for all k. □

THEOREM 9. *Let X have a primarily minimal, semi-normalized strongly asymptotic ℓ_p basis (e_i) for some $1\leqslant p<\infty$. If $1\leqslant p<2$ then X embeds into ℓ_p, and if $p\geqslant 2$ then (e_i) is equivalent to the unit vector basis of ℓ_p.*

Proof. We may assume that X has a 1-unconditional basis (e_i) with a strongly asymptotic ℓ_p constant C.

By Proposition 8 there exists $K<\infty$ such that X K-embeds into each of its tail subspaces associated to $(e_n)_{n\in\mathbb{N}}$. By a result of Johnson [**23**], for each n there exists $N(n)$ such that for any n-dimensional subspace F of any Banach space E with a 1-unconditional basis there exist $N(n)$ normalized disjointly supported vectors $(w_i)_{i=1}^{N(n)}$ (with respect to the basis) such that F is 2-isomorphic to a subspace of $[(w_i)_{i=1}^{N(n)}]$. Let F be an arbitrary finite-dimensional subspace of X and let n be its dimension. Consider $Y=[(e_i)_{i\geqslant f(N(n))}]$. Then Y contains a K-isomorphic copy of X, and thus also of F. By the above result, there exist $N=N(n)$ normalized disjointly supported vectors $(w_i)_{i=1}^N$ of $[(e_i)_{i\geqslant f(N)}]$ such that F is $2K$-isomorphic to a subspace of $W:=[(w_i)_{i=1}^N]$. Therefore, W is C-isomorphic to ℓ_p^N. Thus, F is $2CK$-isomorphic to a subspace of ℓ_p^N. It follows that X is crudely finitely representable in ℓ_p and hence embeds isomorphically into $L_p[0,1]$ [**30**]. The result now follows from Propositions 3 and 5. □

REMARK 10. For $1\leqslant p<2$, we actually obtain that (e_i) may be blocked into a decomposition $\sum_{i=1}^\infty \oplus F_i\cong(\sum_{i=1}^\infty\oplus F_i)_p$, where the F_is embed uniformly into ℓ_p. Indeed, any unconditional basis for a subspace X of ℓ_p, $1\leqslant p<\infty$, may be blocked into such an FDD. For $p>1$ this is due to Johnson and Zippin [**24**], and unconditionality is not required. For $p=1$, this follows for example from Alspach and Odell [**1**, Proposition 31].

As we mentioned in Section 1, we do not know if a positive result similar to Theorem 1 is true for the more general class of asymptotic ℓ_p spaces, $1\leqslant p<\infty$. For example, we do not know what the case is with the Argyros–Deliyanni mixed Tsirelson space X_u [**3**]. Two main ingredients were used in [**11**] to prove the minimality of T^*, namely the universality of ℓ_∞^ns for all finite-dimensional spaces and an appropriate blocking principle. For X_u there is no corresponding blocking principle. On the other hand, it was proved in [**4**] that all of its subspaces contain uniformly ℓ_∞^ns, which makes it impossible to use a local argument as in the case of strongly asymptotic ℓ_p spaces.

Note that there is no version of Theorem 9 for spaces with a primarily minimal FDD (which is defined by replacing the basis (e_i) by an FDD (E_i) throughout Definition 7). Indeed, let $X = (\sum_{n=1}^\infty \oplus \ell_\infty^n)_p$, where $1 \leqslant p < \infty$. Then the natural FDD for X is easily seen to be a primarily minimal strongly asymptotic ℓ_p FDD, but obviously X does not embed into ℓ_p. However, we have the following result for minimal spaces.

Proposition 11. *Suppose that X is minimal and that (E_i) is a strongly asymptotic ℓ_p* FDD *for X, where $1 \leqslant p < \infty$. Then X embeds into ℓ_p.*

Proof. It suffices to show that ℓ_p embeds into X. Choose $e_i \in E_i$ for $i \geqslant 1$ with $\|e_i\| = 1$. Then (e_i) is a strongly asymptotic ℓ_p sequence spannning a minimal subspace Y of X, so Y embeds into ℓ_p by Theorem 9, and hence ℓ_p embeds into X. □

We now present examples of minimal strongly asymptotic ℓ_p spaces that are not isomorphic to ℓ_p, for $1 \leqslant p < 2$. Note that if (e_i) is a strongly asymptotic ℓ_p basis ($1 \leqslant p \leqslant \infty$), then (e_i^*) is a strongly asymptotic ℓ_q ($1/p + 1/q = 1$) basic sequence with the same $f : \mathbb{N} \to \mathbb{N}$. This follows easily from the unconditionality of (e_i) and a standard Hölder's inequality calculation.

Theorem 12. *Let $1 \leqslant p < 2$. There exists a minimal Banach space X with a strongly asymptotic ℓ_p basis (e_i) satisfying the following:*
(i) *X is not isomorphic to ℓ_p;*
(ii) *if $p > 1$ then X^* does not embed into L_q ($1/p + 1/q = 1$).*

Proof. We shall use the following two facts (the first follows from [**26**], and the second follows from the existence, due to Paul Lévy, of s-stable random variables for $1 < s < 2$): firstly, if $s \notin \{2, p\}$ and $M > 0$ then there exists N such that ℓ_p does not contain an M-complemented M-isomorphic copy of ℓ_s^N; secondly, if $p < s < 2$ then ℓ_p contains almost isometric copies (that is, $(1+\varepsilon)$-isomorphic copies for all $\varepsilon > 0$) of ℓ_s^n for all n. For each n, let s_n be defined by the equation $1/s_n := 1/p - (1/p - 1/2)/(2n)$. Note that $p < s_n < 2$ and that $s_n \to p$ rapidly enough to ensure that the standard bases of $\ell_{s_n}^n$ and ℓ_p^n are 2-equivalent (as is easily checked). By the first fact applied to $M = n$ and $s = s_n$, there exists $N(n)$ such that $X_n := \ell_{s_n}^{N(n)}$ is not n-isomorphic to an n-complemented subspace of ℓ_p. Let $X := (\sum_{n=1}^\infty \oplus X_n)_p$ and let (e_i) be the basis of X obtained by concatenation of the standard bases of $X_1, X_2, \ldots$ in that order.

By the second fact each X_n is almost isometric to a subspace of ℓ_p, so X is also almost isometric to a subspace of ℓ_p. Since X_n is 1-complemented in X but is not n-isomorphic to an n-complemented subspace of ℓ_p, it follows that X is not isomorphic to ℓ_p, which proves (i). Property (ii) will follow from (i) and the fact that (e_i) is a strongly asymptotic ℓ_p basis: then X^* is a strongly asymptotic ℓ_q space which is not isomorphic to ℓ_q, and therefore does not embed into L_q by Proposition 3.

Finally, we verify that (e_i) is a strongly asymptotic ℓ_p basis. Suppose that $n \geqslant 1$ and that the vectors $x_1, \ldots, x_n$ are disjointly supported vectors (with respect to (e_i)), which belong to the tail space $(\sum_{j=n}^\infty \oplus X_j)_p$. Write $x_i = \sum_{j=n}^\infty x_i^j$, where $x_i^j \in X_j$. Then

$$\begin{aligned}\|\sum_{i=1}^n x_i\|^p &= \sum_{j=n}^\infty \|\sum_{i=1}^n x_i^j\|^p \\ &= \sum_{j=n}^\infty \Big(\sum_{i=1}^n \|x_i^j\|^{s_j}\Big)^{p/s_j}\end{aligned}$$

(by the disjointness of $x_1^j, \ldots, x_n^j$)

$$\approx \sum_{j=n}^{\infty} \sum_{i=1}^{n} \|x_i^j\|^p$$

(by the 2-equivalence of the standard bases of ℓ_p^n and $\ell_{s_j}^n$ for all $j \geqslant n$)

$$= \sum_{i=1}^{n} \sum_{j=n}^{\infty} \|x_i^j\|^p$$

$$= \sum_{i=1}^{n} \|x_i\|^p. \qquad \square$$

4. *Strongly asymptotic ℓ_p-spaces and complementation*

Let us define a basis $(e_n)_{n\in\mathbb{N}}$ to be primarily complementably minimal if for any partition (I, J) of $\mathbb{N}$, $[e_n]_{n\in\mathbb{N}}$ is isomorphic to a complemented subspace of $[e_n]_{n\in I}$ or of $[e_n]_{n\in J}$. A space X is primarily complementably minimal if, whenever $X = Y \oplus Z$, then either X embeds complementably into Y or X embeds complementably into Z.

Every Banach space which is primary, or which is complementably minimal, is primarily complementably minimal. We now prove a theorem that yields the complementably minimal part of Theorem 1.

Recall that an unconditional basis $(x_n)_{n\in\mathbb{N}}$ of a Banach space is sufficiently lattice-euclidean if it has, for some $C \geqslant 1$ and every $n \in \mathbb{N}$, a C-complemented, C-isomorphic copy of ℓ_2^n and its basis is disjointly supported on $(x_n)_{n\in\mathbb{N}}$. See the work of Casazza and Kalton [8] for a general definition in the lattice setting. Note that strongly asymptotic ℓ_p bases for $p \neq 2$ are not sufficiently lattice-euclidean.

Proposition 13. *Let X be a Banach space with an unconditional, primarily complementably minimal basis $(e_n)_{n\in\mathbb{N}}$. Then there exists $K < \infty$ such that X K-embeds as a K-complemented subspace of its tail subspaces.*

We skip the proof since it is exactly the same as the proof of Proposition 8, *mutatis mutandis*. Note that unconditionality is required to preserve complemented embeddings with uniform constants in the end of the argument.

Theorem 14. *Let X be a primarily complementably minimal Banach space with a semi-normalized strongly asymptotic ℓ_p basis (e_n), $1 \leqslant p \leqslant \infty$. Then (e_n) is equivalent to the unit vector basis of ℓ_p (or c_0 if $p = \infty$).*

Proof. We may assume that $p \neq 2$ and we may also assume that (e_n) is 1-unconditional. By Proposition 13 there exists $K < \infty$ such that X is K-isomorphic to some K-complemented subspace of any tail subspace Y of X. Since $p \neq 2$, X is not sufficiently lattice 1-euclidean; note also that the canonical basis of Y is 1-unconditional. Therefore, we deduce from [8, Theorem 3.6] that (e_n) is c-equivalent to a sequence of disjointly supported vectors in Y^N, for some c and N depending only on X and K. Here Y^N is equipped with the norm $\|(y_i)_{i=1}^N\| = \max_{1\leqslant i\leqslant N} \|y_i\|$ and with the canonical basis obtained from the basis (b_i) of Y with the ordering $(b_1, 0, \ldots, 0), (0, b_1, 0 \ldots, 0), \ldots, (0, \ldots, 0, b_1), (b_2, 0, \ldots, 0)$, etc. It is easy to check that Y^N is also strongly asymptotic ℓ_p with constant C and function f depending only on N and on the strongly asymptotic ℓ_p constant and function of (e_n).

Let $k \in \mathbb{N}$ be arbitrary and let Y be a tail subspace of X such that Y^N is supported after the $f(k)$th vector of the basis of X^N. The sequence $(e_i)_{i \leqslant k}$ is, therefore, c-equivalent to a sequence that is disjointly supported after $f(k)$, so is cC-equivalent to the unit vector basis of ℓ_p^k. □

REMARK 15. We applied [8, Theorem 3.6] with $E_n = \mathbb{N}$ for all n. There is an inaccuracy in the statement of the theorem: the sets E_n do not need to be assumed disjoint. Theorem 3.6 is based on [8, Lemma 3.3], and we want to point out an imprecision in the proof of Lemma 3.3. The inequality on p. 150, line 11, goes the opposite way. In the special case in which we apply Theorem 3.6, however, we have $h_n = |Se_n||T^*e_n|$ and the proof is clear. Actually, as Nigel Kalton has informed us, Lemma 3.3 is true as stated, but one needs a small adjustment in the general case. More precisely, one should define the functions f_n and g_n in a slightly different way. If $0 \leqslant h_n \leqslant |Se_n||T^*e_n|$, we have that h_n can be expessed in the form $h_n = f_n g_n$, where $|f_n| \leqslant |Se_n|$ and $|g_n| \leqslant |T^*e_n|$. Then the proof is correct as it stands.

5. *Some consequences about the number of non-isomorphic subspaces of a Banach space*

The question of the number of mutually non-isomorphic subspaces of a Banach space which is not isomorphic to ℓ_2 was first investigated by Ferenczi and Rosendal [18, 19, 37] (but some ideas originated from an earlier paper of Kalton [28]). A separable Banach space X is said to be ergodic if the relation E_0 of eventual agreement between sequences of 0s and 1s is Borel reducible to isomorphism between subspaces of X; this means that there exists a Borel map f mapping elements of 2^ω to subspaces of X such that $\alpha E_0 \beta$ if and only if $f(\alpha) \simeq f(\beta)$. We refer to [19] or [37] for detailed definitions. We just note here that an ergodic Banach space X must contain 2^ω mutually non-isomorphic subspaces, and furthermore, that it admits no Borel classification of isomorphism classes by real numbers, that is, no Borel map f mapping subspaces of X to reals, with $Y \simeq Z$ if and only if $f(Y) = f(Z)$. A natural conjecture is to ask if any Banach space non-isomorphic to ℓ_2 must be ergodic.

THEOREM 16. *Let $1 \leqslant p \leqslant \infty$ and let X be a Banach space with a semi-normalized strongly asymptotic ℓ_p basis (e_i). Then (e_i) is equivalent to the unit vector basis of ℓ_p (or c_0 if $p = \infty$), or E_0 is Borel reducible to isomorphism between subspaces of X spanned by subsequences of the basis (and in particular there are continuum many mutually non-isomorphic complemented subspaces of X).*

Proof. The basis (e_n) is unconditional. If E_0 is not Borel reducible to isomorphism between subspaces of X spanned by subsequences of the basis, then by Ferenczi and Rosendal [18, 37], there exists $K < \infty$ such that the set $\{\alpha : [e_n]_{\alpha_n=1} \simeq^K X\}$ is comeager in 2^ω. In particular the set A_K of αs such that X K-embeds K-complementably in $[e_n]_{\alpha_n=1}$ is comeager, thus dense, and the proof of Proposition 13 applies to deduce that for some $K' < \infty$, X is K'-isomorphic to some K'-complemented subspace of any tail subspace of X. Then the proof of Theorem 14, if $p \neq 2$, or Theorem 9, if $2 \leqslant p < \infty$, applies. □

A consequence of this result is that the versions T_p of Tsirelson's space are ergodic for $1 < p < \infty$. For T, a stronger result was already proved by Rosendal [36]. Another consequence is that the mixed Tsirelson spaces and their p-convexifications for $1 < p < \infty$ [4] are also ergodic. For a space X with a strongly asymptotic ℓ_p FDD (F_i), we deduce from Theorem 16 that X is ergodic, or that $X = \sum \oplus F_i \simeq (\sum \oplus F_i)_p$ in which case $X \simeq l_p(X)$ by [17, Corollary 2.12] (with the usual modifications when $p = \infty$).

Corollary 17. *Let $1 \leqslant p \leqslant \infty$ and let X be a Banach space with a strongly asymptotic ℓ_p basis. Then X is isomorphic to ℓ_2 or X contains ω_1 non-isomorphic subspaces.*

Proof. Assume that X contains no more than countably many mutually non-isomorphic subspaces. By the above, X is isomorphic to ℓ_p (or c_0 if $p = \infty$). It is known that for $p \neq 2$, ℓ_p contains at least ω_1 non-isomorphic subspaces [**16**, **31**] (in fact, c_0 and ℓ_p, $1 \leqslant p < 2$, are ergodic). So X is isomorphic to ℓ_2. $\square$

Corollary 18. *Let $1 \leqslant p \leqslant \infty$. Let X be a Banach space with a strongly asymptotic ℓ_p* FDD. *Then X is isomorphic to ℓ_2 or X contains ω non-isomorphic subspaces.*

Proof. By the above, we may assume that $X \simeq \ell_2(X)$. If X has finite cotype and X is not isomorphic to ℓ_2, then by Anisca [**2**], $\ell_2(X)$ and therefore X contains at least ω non-isomorphic subspaces. If X does not have finite cotype, it contains ℓ_∞^ns uniformly and therefore X contains copies of the space $Y_p = (\sum_{n \in \mathbb{N}} \ell_p^n)_2$ for any $p \in [1, \infty]$. For $p > 2$, it is easy to check that $\sum_{i=1}^k \|y_i\| \leqslant k^{1/p'} \| \sum_{i=1}^k y_i\|$ for any disjointly supported $y_1, \ldots, y_k$ on the canonical basis of Y_p (see, for example, [**16**, Lemma 2.4]). Therefore by Kalton [**27**, Lemma 9.3] Y_p satisfies a lower r-estimate for any $r > p$ and therefore has cotype r [**32**, p. 88]. On the other hand Y_p contains ℓ_p^ns uniformly and therefore does not have cotype q for $q < p$. Therefore, the spaces Y_p, $p > 2$, are mutually non-isomorphic. $\square$
