ABSTRACT

In this paper, we demonstrate the variation of donut-shaped depletion pattern which influenced by multiple primary aberrations. The simulation is base on a common stimulation emission of depletion (STED) system composed by Gaussian laser and vortex phase plate. The simulation results are helpful guidelines for analyzing the aberration of depletion patterns in real situations.

Keywords: Donut Shaped; Depletion Pattern; Primary Aberration; Gaussian Laser; Phase Plate

1. Introduction

By means of stimulated emission of depletion (STED) technology the far-field optical microscopy has broken the diffraction limit and realized super-resolution of nano scale [1-4], as well as in nano structures fabrications [5-7].

The size of the dark core of depletion pattern determines the resolution of the whole system, and it is believed that a smaller dark spot size a higher resolution of STED system [8,9]. However, in realistic experiment the donut-shaped laser spot is unavoidable to experience influence from primary aberrations (Spherical aberration, coma and astigmatism) even with a well-corrected objective and excellent-alignment. The researchers have revealed the appearances of the annular laser spot influenced by these aberrations respectively [10,11]. Nevertheless, the multiple of primary aberrations will perform in optical system at the same time, and this has not been shown yet. Based on realistic situation we demonstrate and analyze the change of donut-like depletion pattern under multiple primary aberration influence through numerical simulation. The calculation results reveal a more believable appearance of depletion pattern in STED system.

2. Theory

The numerical simulation work is based on circular polarized Gaussian beam, and a vortex phase plate is inserted before high NA objective. Suppose the amplification of objective in simulation is 100 multiple and its NA is 1.4, refractive index of space medium n is 1.52, wavelength \( \lambda \) is 532nm. Figure 1 is the schematic image of optical distribution at point p. The diffracted electric field at this point can be expressed as (1) [11].

\[
E(p) = \begin{pmatrix}
E_x \\
E_y \\
E_z
\end{pmatrix} = -\frac{il}{\lambda} \int_0^{2\pi} \int_0^\pi E_o \sqrt{\cos \theta} A_i(\theta, \phi) \exp [ik(\sin \theta \cos \phi + y \sin \theta \sin \phi + z \cos \theta)]
\]

\[
\times \varphi_i(\theta, \phi) \begin{bmatrix}
\cos \theta \cos^2 \phi + \sin^2 \phi - i \sin \phi \cos \phi (\cos \theta - 1)
\cos \phi \sin \phi (\cos \theta - i) - i (\cos \phi \sin^2 \phi + \cos^2 \phi)
\sin \theta (\cos \theta - i \sin \phi)
\end{bmatrix} \sin \theta d\theta d\phi
\]

OPJ
Here, \( f \) is the focal length of objective, \( l_0 \) represents the amplitude of the electric vector at the optical axis in the object space, \( i \) is the plural, \( k \) stands for the wave number. \( E_0 \) means amplitude of Gaussian beam at the input plane. \( A_i(\theta, \phi) \) is the wavefront aberration function. \( \theta \) is the angle between the optical axis and given ray, \( \theta_{\text{max}} \) stands for the maximal semi-aperture angle of the objective lens, \( \phi \) is the azimuthal coordinate at input plane. \( \varphi(\theta, \phi) \) is the phase delay generated by the phase mask. In addition, \( E_0(\gamma, \theta) = A_0 \exp\left(-\gamma^2 \rho^2\right) \) where \( A_0 \) is the amplitude, \( \gamma \) is the truncation parameter and \( \rho \) is the radial distance of a point from its center normalized by aperture radius of the focusing system. \( \Gamma = a/\omega \) (\( a \) is aperture radius and \( \omega \) is the beam size at waist), and \( \rho = \sin \theta / \sin \theta_{\text{max}} \). Wave aberration function for spherical aberration, coma and astigmatism are expressed as (2), (3) and (4) respectively.

\[
A_1(\theta, \phi) = \exp\left[i k A_1 \rho \right] \quad (2)
\]

\[
A_c(\theta, \phi) = \exp[i k A_c \rho \cos\phi] \quad (3)
\]

\[
A_a(\theta, \phi) = \exp[i k A_a \rho \cos\phi'] \quad (4)
\]

\( A_s, A_c \), and \( A_a \) are respectively coefficient for spherical aberration, coma and astigmatism. The intensity distribution at point \( P \) is written as (5).

\[
I(p) = |E_x|^2 + |E_y|^2 + |E_z|^2 \quad (5)
\]

3. Results and Discussions

In most STED microscopes and photolithography systems the aplanatic objectives are utilized for achieving a high resolution. Therefore the effect of spherical aberration is quite small in realistic systems. Furthermore, in this kind STED system the depletion pattern is insensitive even with a big spherical aberration constant. Thus, only two of the aberrations, coma and astigmatism, will be considered. Assuming coma and astigmatism contribute same mount impacts to transformation, and the values of \( A_c, A_a \) are in the region of 0 to 0.5\( \lambda \) and 0 to 0.3\( \lambda \) respectively. Then we demonstrate the continuous changing of the depletion pattern with various value of \( A_c, A_a \). Figure 2 is the numerical simulation of depletion pattern intensity distribution with different value of \( A_c, A_a \).

Figure 2. Numerical simulation for depletion pattern on focal plane with different \( A_c \) and \( A_a \). (a)(b)(c)(d): \( A_a = 0 \lambda, A_c = 0 \lambda, 0.1 \lambda, 0.25 \lambda, 0.5 \lambda \). (e)(f)(g)(h): \( A_c = 0.1 \lambda, A_a = 0 \lambda, 0.1 \lambda, 0.25 \lambda, 0.5 \lambda \). (i)(j)(k)(l): \( A_a = 0.2 \lambda, A_c = 0 \lambda, 0.1 \lambda, 0.25 \lambda, 0.5 \lambda \). (m)(n)(o)(p): \( A_a = 0.3 \lambda, A_c = 0 \lambda, 0.1 \lambda, 0.25 \lambda, 0.5 \lambda \).
It is obviously in Figure 2(a) to (d) that optical intensity at one side of the donut-shaped depletion beam is gradually weakened with sole influence from strengthening coma. The annular-shape pattern is transformed into a semi-cyclic-shape when \( A_c \) equals to 0.5\( \lambda \). The dark cores of the depletion patterns are maintained in circular shape. In addition, the depletion patterns are in axial symmetry while suffering the influence from coma. Figures 2(a), (e), (i) and (m) illustrate the changing of depletion pattern that sole affected by astigmatism.

In this situation, the depletion patterns are in central symmetry. The annular-shaped pattern is likely tore apart into two pieces with the increasing \( A_a \) value. The dark core is squeezed into line-shaped when \( A_a = 0.3\lambda \). The transformation of the depletion patterns are getting more complex in the combined impact from coma and astigmatism. The dark cores are distorted to irregular ovals in depletion patterns.

It is obvious that in the situation of \( A_c = 0 \) the intensity distribution is axial symmetric. In the cases of \( A_c = 0 \) the intensity distribution are central symmetric. While coma and astigmatism act together the intensity distribution are neither axial symmetric nor central symmetric.

Figures 3, 4 and 5 are drawn in order to better understand how the aberration works to depletion pattern. Figure 4 is the intensity cross section view of Figure 2(a) to (d) along axis x. The optical distribution is asymmetric about axis y, it is noticeable that the intensity of the dark cores has increased a bit. The cross section profiles captured respectively along \( x = y \) and \( x = -y \) are illustrated as Figures 5(a) and (b). The intensity is strong and steep along \( x = y \), while weaker and gentle along \( x = -y \). The intensity at the center of the pattern raises fast with the increasing of \( A_a \).

Figures 3. (a) to (i): Three demission view for intensity distribution changing in the situations of Figure 2(f) to Figure 2(h), Figure 2(f) to Figure 2(h) and Figure 2(n) to Figure 2(p) respectively.
4. Conclusions

Our work demonstrates the variation of donut-shaped depletion pattern under the combined influence of primary optical aberration. The simulation is based on common STED system which utilizing Gaussian beam, vortex phase plate and aplanatic objective. In view of the particular designed objective and spherical aberration is insensitive to this kind of STED system, the effect of spherical aberration is ignored. The depletion patterns that affected by coma and astigmatism are presented in the assumption of the two factors contribute same mount to wavefront aberration. Through our study, the effects of multiple aberrations to donut-shaped depletion patterns are demonstrated visually, and the STED system is quite sensitive with primary aberrations. The simulation results are helpful guidelines for analyzing the aberration of depletion patterns in real situations.
